

03 — Real-world validation report

PauseAm | Status: BLOCKED | 1 October 2026.

Actual totals

Prospective pool: 200+ willing people reported by Kayode. Completed discovery sessions supplied: 0. Documented PS2 interactions: 0 of the required minimum 50. Distinct validated participants: 0. Completed fluent reviews: 0. English: 0 interactions. Yoruba: 0. Hausa: 0. Igbo: 0. Voice success, WER, comprehension, retention and impact: not measured.

Engineering tests, authored prompts and browser automation are excluded. Prospective testers and device-local feedback are not independently documented human interactions. No scores, responses or participant evidence have been invented.

Method

The discovery pack defines 6–8 varied 15-minute sessions, voluntary consent, adult participants, neutral questions and non-sensitive task scenarios. Kayode agreed to arrange sessions and reports reviewers are available. Availability is not completion. Record findings and revise the product before locking features. A separate business mode and screenshots remain deferred.

Final-round criteria were declared before results: at least 50 real PS2 voice interactions; target 10 per language; 80% unassisted task completion; 90% correct action comprehension; 80% unassisted source finding; zero critical harmful advice or secret exposure. These are targets, not findings. Report all failures.

Evidence controls

Use interactions-template.csv. Completed records go in private/research/, outside public Git: consent/date, random participant code, language, device/network, journey, build, model/revision, trace, completion, correction counts, comprehension, feedback codes, defect/change IDs and observer attestation. No banking secrets.

An aggregation script checks schema, duplicate IDs and arithmetic. It cannot prove a human participated. An observer must verify provenance; publish only redacted aggregates. Separate scheduling contacts from research. Confirm the proposed 90-day raw-log retention and participant deletion procedure before collection.

Limitations

The decision-companion hypothesis remains untested. No actual finding supports or rejects it yet. This honest status report does not satisfy the required completed validation. No impact or language-level success claim can be made.
